# Tamely Eisenstein field with prime power discriminant

Toru KOMATSU

#### § 1. Introduction

In this paper we study a non-Galois, totally and tamely ramified field with prime power discriminant and present a method for the constructions of such fields with some properties. The existence of such a field is an interesting problem not only for algebraic number theory but also for theory of association scheme (see Theorem 1.1, Hanaki-Uno [4]). We also study the Galois groups of the Galois closure extensions of such fields.

Let p be a prime number. For a monic polynomial  $f(X) = \sum_{i=0}^{d} a_i X^i \in \mathbb{Q}[X]$  of degree d we say that f(X) is a p-Eisenstein polynomial if the coefficients  $a_i$  satisfy  $p \mid a_i$  for  $0 \leq i \leq d-1$  and  $p^2 \nmid a_0$ . The zeros of a p-Eisenstein polynomial are called p-Eisenstein numbers. For a number field K we say that K is a p-Eisenstein field if K is generated by a p-Eisenstein number over  $\mathbb{Q}$ . It is known that  $K/\mathbb{Q}$  is totally ramified at p if and only if K is a p-Eisenstein field (cf. [2]). We define six conditions (1) to (6) on an algebraic number field K with degree  $d = [K : \mathbb{Q}]$  by

- (1) the field K is not a Galois extension over  $\mathbb{Q}$ ,
- (2) the degree d is a divisor of p-1,
- (3) the discriminant  $\operatorname{disc}(K/\mathbb{Q})$  of K is equal to  $\pm p^{d-1} \equiv 1 \pmod{4}$ ,
- (4) the field K is a p-Eisenstein field,
- (5) the extension  $K/\mathbb{Q}$  is unramified at all prime numbers other than p,
- (6) the field K is totally real or totally imaginary.

We note that for an algebraic number field K with (2), it holds (3) if and only if K satisfies (4) and (5) (see Proposition 2.3). Hanaki and Uno showed the following theorem on the classification of association schemes.

**Theorem 1.1** (Hanaki-Uno [4]). Let (X, G) be an association scheme of prime order p with  $\sharp G = d+1$ . If there exist no algebraic number fields which satisfy all of the six conditions (1) to (6), then (X, G) is algebraically isomorphic to a cyclotomic scheme.

The following problem is natural to be considered.

**Problem 1.2** (Hanaki [3]). Are there any algebraic number fields K satisfying all of the six conditions (1) to (6) ?

In this paper we obtain an affirmative answer for the Problem 1.2 with explicit construction. We give a method for the constructions of fields satisfying all the six conditions (1) to (6). Let  $\zeta = \zeta_p$  be a primitive *p*-th root of unity in  $\overline{\mathbb{Q}}$ . Let *d* be a positive divisor of p-1. Let *L* be the subfield of  $\mathbb{Q}(\zeta)$  with  $[L:\mathbb{Q}] = d$  and *k* a subfield of *L* whose degree  $[k:\mathbb{Q}]$  is denoted by *n*. It holds that  $n \mid d \mid p-1$ . Let *r* be the ratio  $d/n \in \mathbb{Z}$  which is equal to [L:k]. We assume that there exists an unramified cyclic extension *M* of *k* with degree *r*. Let *E* be the composite field *LM* of *L* and *M*. Then *E* is a Galois extension of *k* whose Galois group  $G_0 = \operatorname{Gal}(E/k)$  is isomorphic to  $(\mathbb{Z}/r\mathbb{Z})^2$ . Let  $G_1$  and  $G_2$  be subgroups of  $G_0$ satisfying  $E^{G_1} = L$  and  $E^{G_2} = M$ , respectively. Let  $G_3$  be a subgroup of  $G_0$  such that  $G_3 \cap G_1 = G_3 \cap G_2 = 1$  and  $G_3 \simeq \mathbb{Z}/r\mathbb{Z}$ . We define a number field *K* to be the subfield  $E^{G_3}$  of *E* fixed by  $G_3$ .

**Theorem 1.3.** The field K satisfies all of the six conditions (1) to (6) provided  $r \ge 2$ . If d divides (p-1)/2, then K is totally real with  $\operatorname{disc}(K/\mathbb{Q}) = p^{d-1}$ . When d is not a divisor of (p-1)/2, the field K is totally imaginary and  $\operatorname{disc}(K/\mathbb{Q}) = (-1)^{(p-1)/2}p^{d-1} = (-1)^{d/2}p^{d-1}$ .

For example we may have (p, n, r) = (229, 2, 3) and (277, 3, 2) (see § 5 for the explicit constructions of K and the definition polynomials of K). The case r = 1 implies that K = L, which is a cyclic field satisfying the five conditions (2) to (6).

Let K be an algebraic number field with the five conditions (2) to (6). We denote by  $\widetilde{K}$  the Galois closure extension of K over  $\mathbb{Q}$  and  $G = \operatorname{Gal}(\widetilde{K}/\mathbb{Q})$ . Note that G is isomorphic to a transitive subgroup of the symmetric group  $\mathfrak{S}_d$  with degree d.

**Proposition 1.4** (Proposition 3.6). If d is odd, then G is contained in the alternating group  $\mathfrak{A}_d$  with degree d. When d is a prime number, the group G is simple.

For a positive integer  $d \in \mathbb{Z}$  with  $d \geq 2$  let us denote by  $\mathcal{T}_d$  the family of all the transitive subgroup of the symmetric group  $\mathfrak{S}_d$  with degree d. For integers  $d \in \mathbb{Z}$  with  $2 \leq d \leq 7$  we define subfamilies  $\mathcal{G}_d$  of  $\mathcal{T}_d$  by

$$\begin{array}{ll} \mathcal{G}_2 = \{\mathcal{C}_2\}, & \mathcal{G}_3 = \{\mathcal{C}_3\}, & \mathcal{G}_4 = \{\mathcal{C}_4, \mathfrak{S}_4\}, & \mathcal{G}_5 = \{\mathcal{C}_5, \mathfrak{A}_5\}, \\ \mathcal{G}_6 = \{\mathcal{C}_6, \mathcal{D}_3 \times \mathcal{C}_3, \mathfrak{A}_4 \times \mathcal{C}_2, \mathfrak{S}_5, \mathfrak{S}_6\}, & \mathcal{G}_7 = \{\mathcal{C}_7, \mathrm{PSL}_2(\mathbb{F}_7), \mathfrak{A}_7\} \end{array}$$

respectively. Here  $\mathcal{C}_m$ ,  $\mathcal{D}_m$ ,  $\mathfrak{A}_m$  and  $\mathfrak{S}_m$  are the cyclic group, the dihedral group, the alternating group and the symmetric group of degree m with order m, 2m, m!/2 and m!, respectively. The group  $\mathrm{PSL}_2(\mathbb{F}_7)$  is the projective special linear group of  $2 \times 2$  matrices over the finite field  $\mathbb{F}_7$  with 7 elements.

**Proposition 1.5** (Proposition 3.7). The group G is isomorphic to a group in the family  $\mathcal{G}_d$  when  $2 \leq d \leq 7$ .

In § 2 we study the construction of an algebraic number field with the six conditions (1) to (6). In § 3 we study the Galois group of the Galois closure extension of a field satisfying the five conditions (2) to (6). In § 4 we study a method for finding *p*-Eisenstein numbers in a *p*-Eisenstein field. In § 5 we present some numerical examples of fields satisfying the six conditions (1) to (6) with explicit definition polynomials.

Acknowledgement. The author is grateful to Doctor Yasushi Mizusawa for discussing on Problem 1.2. He is supported by the 21st Century COE Program "Development of Dynamic Mathematics with High Functionality".

### § 2. Construction of a non-Galois Eisenstein field

In this section we study the construction of an algebraic number field satisfying the six conditions (1) to (6). We prepare the following fundamental lemmas on the ramifications. Let F be an algebraic number field of finite degree.

**Lemma 2.1** (cf. [2]). The extension  $F/\mathbb{Q}$  is totally ramified at a prime number l if and only if F is a l-Eisenstein field.

Let l be a prime number. For a prime ideal  $\mathfrak{l}$  of F above l we denote by  $e_{F,\mathfrak{l}}$  the ramification index of  $\mathfrak{l}$  in  $F/\mathbb{Q}$  and by  $f_{F,\mathfrak{l}}$  the degree of the residue field  $\mathcal{O}_F/\mathfrak{l}$  over  $\mathbb{F}_l$ . Let us define  $e_{F,\mathfrak{l}}$  to be the least common multiple of the indices  $e_{F,\mathfrak{l}}$  and  $f_{F,\mathfrak{l}}$  to be the sum of the degrees  $f_{F,\mathfrak{l}}$  where  $\mathfrak{l}$  runs through all of the prime ideals  $\mathfrak{l}$  of F above l.

**Lemma 2.2** (cf. [2]). If  $e_{F,l}$  is not divisible by l, then l-adic valuation of the discriminant disc $(F/\mathbb{Q})$  is equal to  $d - f_{F,l}$ .

Lemmas 2.1 and 2.2 imply

**Proposition 2.3.** For an algebraic number field F of degree d less than a prime number p, the discriminant  $\operatorname{disc}(F/\mathbb{Q})$  is equal to  $\pm p^{d-1} \equiv 1 \pmod{4}$  if and only if  $F/\mathbb{Q}$  is a p-Eisenstein field and is unramified at all prime numbers other than p.

Let the notation be the same as for Theorem 1.3 in the Introduction. Let  $\mathfrak{p}$  be a prime ideal E above p. For subfields F of E we denote by  $\mathfrak{p}_F$  the prime ideal  $\mathfrak{p} \cap F$  of F below  $\mathfrak{p}$ , respectively.

**Lemma 2.4.** The degree  $[K : \mathbb{Q}]$  is equal to d. The extension  $K/\mathbb{Q}$  is a p-Eisenstein field and is unramified at all prime numbers except for p.

Proof. The degree  $[K : \mathbb{Q}]$  of K is equal to  $[E : k][E : K]^{-1}[k : \mathbb{Q}] = r^2r^{-1}n = d$ . The prime ideal  $\mathfrak{p}_L$  of L is totally ramified in the extension  $L/\mathbb{Q}$  and so is in L/k. On the other hand,  $\mathfrak{p}_M$  is unramified in M/k. Thus the inertia field of  $\mathfrak{p}$  in E/k is equal to M. Since  $G_3 \cap G_2 = 1$ , one sees that  $\mathfrak{p}$  is unramified in E/K. This means that  $\mathfrak{p}$  is totally ramified in K/k and so is  $\mathfrak{p}_K$ . Here  $\mathfrak{p}_k$  is totally ramified in  $k/\mathbb{Q}$ . Thus  $\mathfrak{p}_K$  is totally ramified in  $K/\mathbb{Q}$ . Lemma 2.1 implies that K is a p-Eisenstein field. Since L and M are unramified over  $\mathbb{Q}$  at all prime numbers except for p, so is the subfield K of the composite field E = LM.

**Corollary 2.5.** The discriminant  $\operatorname{disc}(K/\mathbb{Q})$  of K is equal to  $\pm p^{d-1} \equiv 1 \pmod{4}$ .

The field K is Galois over k with  $\operatorname{Gal}(K/k) \simeq \mathbb{Z}/r\mathbb{Z}$ . Let  $k_0$  be a subfield of k so that  $K/k_0$  is Galois.

**Lemma 2.6.** The field  $k_0$  has a cyclic extension with degree r which is unramified at all prime ideals of  $k_0$  and which is contained in E.

Proof. Let  $r_0$  denote the degree of the extension  $K/k_0$ . Since  $\mathfrak{p}_K$  is totally and tamely ramified in  $K/k_0$ , the Galois group  $\operatorname{Gal}(K/k_0)$  is cyclic. This means that  $\operatorname{Gal}(L/k_0) \simeq \operatorname{Gal}(K/k_0) \simeq \mathbb{Z}/r_0\mathbb{Z}$ . It follows from  $G_3 \cap G_1 = 1$  that E = LK. Thus E = LK is abelian over  $k_0$ . This implies that  $\operatorname{Gal}(E/k) \simeq (\mathbb{Z}/r\mathbb{Z})^2$  and  $\operatorname{Gal}(k/k_0) \simeq \mathbb{Z}/r_1\mathbb{Z}$  where  $r_1 = r_0/r$ . Let  $M_0$  be the inertia field of  $\mathfrak{p}$  in  $E/k_0$ . Since  $E/k_0$  is abelian, the prime ideal  $\mathfrak{p}_{k_0}$  of  $k_0$  is unramified in  $M_0/k_0$ . Here  $\mathfrak{p}_{k_0}$  is a unique prime ideal of  $k_0$  above p. This means that  $M_0$  is an abelian extension of  $k_0$  which is unramified at all prime ideals of  $k_0$ . The prime ideal  $\mathfrak{p}$  is totally ramified in  $L/k_0$  and is unramified in E/L. Thus it holds that  $[M_0 : k_0] = [E : L] = r$ . By considering the ramification above p, one has  $L \cap M_0 = k_0$ . It follows from  $[L : k_0][M_0 : k_0] = [E : k_0]$  that  $E = LM_0$ . Thus it satisfies that  $\operatorname{Gal}(M_0/k_0) \simeq$  $\operatorname{Gal}(E/L) \simeq \mathbb{Z}/r\mathbb{Z}$ . Hence  $M_0$  is a cyclic extension of  $k_0$  with degree r which is unramified at all prime ideals of  $k_0$ . By the construction one has  $M_0 \subset E$ .

### **Proposition 2.7.** The field K is a non-Galois extension of $\mathbb{Q}$ if $r \geq 2$ .

Proof. When  $K/\mathbb{Q}$  is Galois, one may have  $k_0 = \mathbb{Q}$ . Lemma 2.6 means that  $\mathbb{Q}$  has a cyclic extension of degree r which is unramified at all prime numbers. It is well-known due to Minkowski's theorem that  $\mathbb{Q}$  has no non-trivial extensions which is unramified at all prime numbers. Thus one has r = 1. This shows that  $K/\mathbb{Q}$  is non-Galois provided  $r \geq 2$ .

Proof of Theorem 1.3. Lemma 2.4, Corollary 2.5 and Proposition 2.7 verify that K satisfies the five conditions (1) to (5) when  $r \ge 2$ . If d divides (p-1)/2, then the fields L and M are totally real and so is the subfield K of the composite field E = LM. The discriminant  $\operatorname{disc}(K/\mathbb{Q})$  is positive since K is totally real. Let us assume that d is not a divisor of (p-1)/2. Then L is totally imaginary. When r is odd, the field k is totally imaginary and so is the extension K. For the case that r is even, k is totally real and E is totally imaginary. By the same argument as that for the prime number p in the proof of Lemma 2.4, one can see that K/k is ramified at all infinite places of k, that is, K is totally imaginary. Thus K satisfies the condition (6). The assumption  $d \nmid (p-1)/2$  means that  $v_2(d) = v_2(p-1)$  and  $(-1)^{d/2} = (-1)^{(p-1)/2}$ . Hence we have shown Theorem 1.3.

### § 3. Galois closure extension of an Eisenstein field

In this section we study the Galois group of the Galois closure extension of a field satisfying the five conditions (2) to (6). Let p be a prime number and da positive divisor of p - 1. Let K be a field with the five conditions (2) to (6). Let  $\widetilde{K}$  denote the Galois closure extension of K over  $\mathbb{Q}$ , that is,  $\widetilde{K}$  is the minimal extension of K which is Galois over  $\mathbb{Q}$ . Let  $\mathfrak{p}$  be the prime ideal of K above p.

### **Lemma 3.1.** The extension $\widetilde{K}/K$ is unramified at $\mathfrak{p}$ .

Proof. Let z be a p-Eisenstein number such that  $K = \mathbb{Q}(z)$ . Let  $f(X) = \sum_{i=0}^{d} a_i X^i$ be the minimal polynomial of z over  $\mathbb{Q}$ . Then it holds that  $v_p(a_0) = 1$  and  $v_p(a_i) \ge 1$ for  $1 \le i \le d-1$  where  $v_p$  is the p-adic valuation of  $\mathbb{Q}$ . Let us put  $f_0(X) = z^{-d}f(zX) \in K[X]$ . Then the minimal splitting field  $\operatorname{Spl}_K f_0(X)$  of  $f_0(X)$  over K is equal to that of f(X) over  $\mathbb{Q}$ . Let  $b_i \in K$  be numbers such that  $f_0(X) = \sum_{i=0}^{d} b_i X^i$ . This implies that  $b_d = 1$ ,  $v_p(b_0) = 0$  and  $v_p(b_i) \ge 1$  for  $1 \le i \le d-1$  where  $v_p$  is the **p**-adic valuation of K. Let  $\beta \in \overline{\mathbb{Q}}$  be a d-th root of  $-b_0$ , that is,  $\beta^d + b_0 = 0$ . Now put  $N = K(\zeta_d, \beta)$  where  $\zeta_d$  is a primitive d-th root of unity in  $\overline{\mathbb{Q}}$ . The extension N/Kis unramified at  $\mathfrak{p}$  since  $v_p(b_0) = v_p(d) = 0$ . Let  $\mathfrak{P}$  be a prime ideal of N above  $\mathfrak{p}$ . Hensel's lemma shows that  $\mathfrak{P}$  splits completely in the extension  $\operatorname{Spl}_N f_0(X)/N$ , in particular,  $\mathfrak{P}$  is unramified in  $\operatorname{Spl}_N f_0(X)/N$ . Thus  $\mathfrak{p}$  is unramified in  $\operatorname{Spl}_N f_0(X)/K$ and so is in the subextension  $\operatorname{Spl}_K f_0(X)/K$ . Here  $\operatorname{Spl}_K f_0(X) = \operatorname{Spl}_Q f(X)$  is a Galois extension of  $\mathbb{Q}$  containing K. This means that  $K \subseteq \widetilde{K} \subseteq \operatorname{Spl}_{\mathbb{Q}} f(X)$ . Hence  $\widetilde{K}/K$  is unramified at  $\mathfrak{p}$ .

## **Proposition 3.2.** The extension $\widetilde{K}/K$ is unramified.

Proof. Lemma 3.1 implies that  $\widetilde{K}/K$  is unramified at  $\mathfrak{p}$ . Since  $K/\mathbb{Q}$  is unramified at all prime numbers other than p, so are the conjugate fields of K over  $\mathbb{Q}$ . Thus the composite field  $\widetilde{K}$  of the fields conjugate to K over  $\mathbb{Q}$  is unramified at all prime numbers other than p. It follows from the definition that K satisfies the condition (6) if and only if  $\widetilde{K}/K$  is unramified at all infinite places of K. Hence  $\widetilde{K}/K$  is unramified.

Let G denote the Galois group of  $\operatorname{Gal}(\widetilde{K}/\mathbb{Q})$ . Let  $\widetilde{\mathfrak{p}}$  be a prime ideal of  $\widetilde{K}$  above  $\mathfrak{p}$ . Let  $\theta$  be a generator of K over  $\mathbb{Q}$ , that is,  $K = \mathbb{Q}(\theta)$ . The minimal polynomial f(X)of  $\theta$  over  $\mathbb{Q}$  has degree d and satisfies that  $\operatorname{Spl}_{\mathbb{Q}}f(X) = \widetilde{K}$ . Thus G is isomorphic to a transitive subgroup of the symmetric group  $\mathfrak{S}_d$  with degree d. Let  $\{\theta_j\}_{j=1}^d$  be the zero set of f(X), that is,  $f(X) = \prod_{j=1}^d (X - \theta_j)$ . In the following we identify Gwith the image of an injective homomorphism  $G \to \mathfrak{S}_d$ ,  $\sigma \mapsto \tau$  where  $\sigma \in G$  and  $\tau \in \mathfrak{S}_d$  have relations  $\sigma(\theta_j) = \theta_{\tau(j)}$  for all  $1 \leq j \leq d$ .

### Lemma 3.3. The group G has an element of order d.

Proof. Since K is p-Eisenstein with degree d, the ramification index of  $\mathfrak{p}$  in  $K/\mathbb{Q}$  is equal to d. Lemma 3.1 implies that  $\widetilde{K}/K$  is unramified at  $\mathfrak{p}$ . Thus the ramification index of p in  $\widetilde{K}/\mathbb{Q}$  is equal to d. Note that the ramification of p in  $\widetilde{K}/\mathbb{Q}$  is tame for  $p \nmid d$ . This means that the inertia group of  $\widetilde{\mathfrak{p}}$  in  $\widetilde{K}/\mathbb{Q}$  is isomorphic to  $\mathcal{C}_d$ . This shows that G contains  $\mathcal{C}_d$  as a subgroup.

Let us define a positive integer  $\lambda$  to be the minimal prime divisor of d.

**Lemma 3.4.** If  $G_1$  is a subgroup of G with index  $[G:G_1] < \lambda$ , then  $G = G_1$ .

Proof. Let  $K_1$  be the fixed field  $\widetilde{K}^{G_1}$  of  $\widetilde{K}$  by  $G_1$ . Let  $\mathfrak{p}_1$  be the prime ideal of  $K_1$ below  $\widetilde{\mathfrak{p}}$ . If  $[G:G_1] < \lambda$ , then the ramification index of  $\mathfrak{p}_1$  in  $K_1/\mathbb{Q}$  is a divisor of dless than  $\lambda$ , which is equal to 1. This means that  $\mathfrak{p}_1$  is unramified in  $K_1/\mathbb{Q}$ . Thus  $K_1/\mathbb{Q}$  is an extension of degree  $[G:G_1]$  which is unramified at all prime numbers. By Minkowski's theorem, we have  $[G:G_1] = 1$ . **Lemma 3.5.** Let  $G_1$  be a proper, normal subgroup of G. Then d and the index  $[G:G_1]$  have a common prime divisor. If the group  $G/G_1$  is abelian, then  $G/G_1$  is a subgroup of  $C_d$ .

Proof. Since  $G_1$  is a normal subgroup of G, the fixed field  $K_1 = \tilde{K}^{G_1}$  is a Galois extension whose Galois group  $\operatorname{Gal}(K_1/\mathbb{Q})$  is isomorphic to the quotient group  $G/G_1$ . The ramification index of p in  $K_1/\mathbb{Q}$  divides d and  $[G:G_1]$ . When d and  $[G:G_1]$ are relatively prime to each other, the extension  $K_1/\mathbb{Q}$  is unramified at p. Thus Minkowski's theorem implies that  $K_1 = \mathbb{Q}$  and  $G_1 = G$ . If  $G/G_1$  is abelian, then so is  $K_1/\mathbb{Q}$ . By Minkowski's theorem one can see that  $\operatorname{Gal}(K_1/\mathbb{Q})$  is isomorphic to a subgroup of  $\mathcal{C}_d$ .

**Proposition 3.6** (Proposition 1.4). If d is odd, then G is contained in the alternating group  $\mathfrak{A}_d$  with degree d. When d is a prime number, the group G is simple.

*Proof.* Let sgn :  $\mathfrak{S}_d \to \{\pm 1\}$  be the signature map so that  $\operatorname{sgn}(\sigma) = 1$  (resp. -1) if  $\sigma$  is an even (resp. an odd) permutation. Then the map sgn is a group homomorphism and the kernel  $G_1$  of the restricted map  $\operatorname{sgn}|_G$  to G is a normal subgroup of G. When  $G \not\subseteq \mathfrak{A}_d$ , one has that  $\operatorname{sgn}(G) = \{\pm 1\}$  and  $[G: G_1] = 2$ . Lemmas 3.4 and 3.5 imply that  $2 \mid d$ . Thus we have  $G \subseteq \mathfrak{A}_d$  provided d is odd. We assume that d is equal to a prime number l. Let  $G_1$  be a proper, normal subgroup of G and denote by  $K_1$  the fixed field  $\widetilde{K}^{G_1}$  of  $\widetilde{K}$  by  $G_1$ . Note that  $K_1$  is Galois over  $\mathbb{Q}$  since  $G_1$  is normal of G. It follows from Lemma 3.5 that l divides the degree  $[K_1:\mathbb{Q}] = [G:G_1]$  of  $K_1/\mathbb{Q}$ . Here  $K \cap K_1$  is equal to  $\mathbb{Q}$  or K since  $K/\mathbb{Q}$  is of prime degree l. Now suppose that  $K \cap K_1 = \mathbb{Q}$ . Galois theory implies that the lift  $KK_1/K$  of the Galois extension  $K_1/\mathbb{Q}$  by K is a Galois extension whose Galois group is isomorphic to  $\operatorname{Gal}(K_1/K \cap K_1) = \operatorname{Gal}(K_1/\mathbb{Q})$ . This means that  $[KK_1 : K]$ and  $[K:\mathbb{Q}]$  are both divisible by l. Note that  $KK_1$  is a subfield of  $\widetilde{K}$ . Then one has that  $[\widetilde{K}:\mathbb{Q}] = [\widetilde{K}:KK_1][KK_1:K][K:\mathbb{Q}] \equiv 0 \pmod{l^2}$ . On the other hand, G satisfies  $v_l(\sharp G) \leq v_l(\sharp \mathfrak{S}_l) = 1$  for  $G \subseteq \mathfrak{S}_l$ . It is a contradiction. Thus we have  $K \cap K_1 = K$ , which means that  $K \subseteq K_1$ . This implies that  $K_1 = \widetilde{K}$  and  $G_1 = 1$ due to the minimality of the Galois closure  $\tilde{K}$ . Hence the group G is simple. 

For a positive integer  $d \in \mathbb{Z}$  with  $d \geq 2$  let  $\mathcal{T}_d$  be the family of all the transitive subgroup of  $\mathfrak{S}_d$ . For integers  $d \in \mathbb{Z}$  with  $2 \leq d \leq 7$  we define subfamilies  $\mathcal{G}_d$  of  $\mathcal{T}_d$ as in the Introduction, that is,

$$\begin{array}{ll} \mathcal{G}_2 = \{\mathcal{C}_2\}, & \mathcal{G}_3 = \{\mathcal{C}_3\}, & \mathcal{G}_4 = \{\mathcal{C}_4, \mathfrak{S}_4\}, & \mathcal{G}_5 = \{\mathcal{C}_5, \mathfrak{A}_5\}, \\ \mathcal{G}_6 = \{\mathcal{C}_6, \mathcal{D}_3 \times \mathcal{C}_3, \mathfrak{A}_4 \times \mathcal{C}_2, \mathfrak{S}_5, \mathfrak{S}_6\}, & \mathcal{G}_7 = \{\mathcal{C}_7, \mathrm{PSL}_2(\mathbb{F}_7), \mathfrak{A}_7\}. \end{array}$$

**Proposition 3.7** (Proposition 1.5). We have  $G \in \mathcal{G}_d$  for  $2 \leq d \leq 7$ .

The families  $\mathcal{T}_d$  for  $2 \leq d \leq 7$  are well-known.

**Lemma 3.8** (cf. [1] §6.3). We have

$$\begin{split} \mathcal{T}_{2} &= \{ \mathcal{C}_{2} \}, \\ \mathcal{T}_{3} &= \{ \mathcal{C}_{3}, \mathfrak{S}_{3} \}, \\ \mathcal{T}_{4} &= \{ \mathcal{C}_{4}, (\mathcal{C}_{2})^{2}, \mathcal{D}_{4}, \mathfrak{A}_{4}, \mathfrak{S}_{4} \}, \\ \mathcal{T}_{5} &= \{ \mathcal{C}_{5}, \mathcal{D}_{5}, \mathcal{M}_{20}, \mathfrak{A}_{5}, \mathfrak{S}_{5} \}, \\ \mathcal{T}_{6} &= \{ \mathcal{C}_{6}, \mathfrak{S}_{3}, \mathcal{D}_{6}, \mathfrak{A}_{4}, \mathcal{D}_{3} \times \mathcal{C}_{3}, \mathfrak{A}_{4} \times \mathcal{C}_{2}, \mathfrak{S}_{4}^{-}, \mathfrak{S}_{4}^{+}, (\mathcal{D}_{3})^{2}, \\ & (\mathcal{C}_{3})^{2} \rtimes \mathcal{C}_{4}, \mathfrak{S}_{4} \times \mathcal{C}_{2}, \mathfrak{A}_{5}, (\mathcal{C}_{3})^{2} \rtimes \mathcal{D}_{4}, \mathfrak{S}_{5}, \mathfrak{A}_{6}, \mathfrak{S}_{6} \}, \\ \mathcal{T}_{7} &= \{ \mathcal{C}_{7}, \mathcal{D}_{7}, \mathcal{M}_{21}, \mathcal{M}_{42}, \mathrm{PSL}_{2}(\mathbb{F}_{7}), \mathfrak{A}_{7}, \mathfrak{S}_{7} \}, \end{split}$$

where  $\mathcal{M}_{dm}$  is the metagroup  $\mathcal{C}_d \rtimes \mathcal{C}_m$ . Here  $\mathfrak{S}_4^+$  and  $\mathfrak{S}_4^-$  are groups isomorphic to  $\mathfrak{S}_4$  whose images of the signature map are equal to  $\{1\}$  and  $\{\pm 1\}$ , respectively.

Proof of Proposition 3.7. It is easy to see that the groups  $\mathfrak{S}_3$ ,  $\mathcal{D}_5$ ,  $\mathcal{M}_{20}$ ,  $\mathfrak{S}_5$ ,  $\mathcal{D}_7$ ,  $\mathcal{M}_{21}$ ,  $\mathcal{M}_{42}$  and  $\mathfrak{S}_7$  are not simple. Thus Proposition 3.6 shows the assertions of the cases d = 3, 5 and 7. Let us assume d = 4. Here  $(\mathcal{C}_2)^2$  has no elements of order 4. Lemma 3.3 means that  $G \not\simeq (\mathcal{C}_2)^2$ . The groups  $\mathcal{D}_4$  (resp.  $\mathfrak{A}_4$ ) have normal subgroups  $H \simeq \mathcal{C}_2$  (resp.  $(\mathcal{C}_2)^2$ ) such that  $\mathcal{D}_4/H \simeq (\mathcal{C}_2)^2$  (resp.  $\mathcal{C}_3$ ). Lemma 3.5 implies that  $G \not\simeq \mathcal{D}_4, \mathfrak{A}_4$ . This shows the assertion for d = 4. Next consider the case d = 6. One can see that the groups  $\mathfrak{S}_3, \mathfrak{A}_4, \mathfrak{S}_4^-, \mathfrak{S}_4^+, \mathfrak{A}_5, \mathfrak{A}_6$  have no elements of order 6, respectively. The groups  $\mathcal{D}_6, (\mathcal{D}_3)^2, \mathfrak{S}_4 \times \mathcal{C}_2$  and  $(\mathcal{C}_3)^2 \rtimes \mathcal{D}_4$  have normal subgroups whose quotient groups are isomorphic to  $(\mathcal{C}_2)^2$ , respectively. The group  $(\mathcal{C}_3)^2 \rtimes \mathcal{C}_4$  has a normal subgroup whose quotient group is isomorphic to  $\mathcal{C}_4$ . Lemmas 3.3 and 3.5 prove the assertion for d = 6.

### § 4. Eisenstein number in an Eisenstein field

In this section we study a method for finding *p*-Eisenstein numbers in a *p*-Eisenstein field. Let K be a *p*-Eisenstein field with degree  $d \ge 2$  and  $\mathfrak{p}$  the prime ideal of K above p. Let  $\mathcal{O}_{K,\mathfrak{p}}$  be the completion at  $\mathfrak{p}$  of the ring  $\mathcal{O}_K$  of integers in K.

Let  $\{x_j\}_{j=1}^d$  be a free basis of  $\mathcal{O}_{K,\mathfrak{p}}$  over  $\mathbb{Z}_p$ , that is,  $\mathcal{O}_{K,\mathfrak{p}} = \{\sum_{j=1}^d m_j x_j | m_j \in \mathbb{Z}_p\}$ . One may assume  $v_{\mathfrak{p}}(x_1) = 0$ . Since  $\mathcal{O}_K/\mathfrak{p} \simeq \mathbb{F}_p$ , there exist rational integers  $c_j \in \mathbb{Z}$ such that  $x_1c_j \equiv x_j \pmod{\mathfrak{p}}$  for  $2 \leq j \leq d$ . Now put  $z_j = x_j - x_1c_j \in \mathcal{O}_K$  for  $2 \leq j \leq d$ , respectively. Note that  $z_j \neq 0$  since the basis  $\{x_j\}_{j=1}^d$  is free.

**Lemma 4.1.** There exists a p-Eisenstein number z in the finite set  $\{z_j | j \in \mathbb{Z}, 2 \leq j \leq d\}$  such that  $K = \mathbb{Q}(z)$ .

*Proof.* It follows from  $c_j \in \mathbb{Z}$  that  $\{x_1\} \cup \{z_j\}_{j=2}^d$  is also a free basis of  $\mathcal{O}_{K,\mathfrak{p}}$  over  $\mathbb{Z}_p$ . Let  $\pi$  be a number in  $\mathcal{O}_K$  such that  $v_{\mathfrak{p}}(\pi) = 1$  where  $v_{\mathfrak{p}}$  is the  $\mathfrak{p}$ -adic valuation of K. Then there exist numbers  $m_j \in \mathbb{Z}_p$  such that  $\pi = m_1 x_1 + \sum_{j=2}^d m_j z_j$ . Let us denote  $\min\{v_{\mathfrak{p}}(z_j)|j \in \mathbb{Z}, 2 \leq j \leq d\}$  by  $\mu$ . Then one has  $\mu \geq 1$  for  $z_j \in \mathfrak{p}$ . Now suppose  $\mu \geq 2$ . If  $v_{\mathfrak{p}}(m_1) = 0$ , then  $v_{\mathfrak{p}}(\pi) = 0$ , which is a contradiction. When  $v_{\mathfrak{p}}(m_1) \ge 1$ , one has  $v_{\mathfrak{p}}(\pi) \ge \min\{v_{\mathfrak{p}}(m_1), \mu\} \ge 2$  for  $v_{\mathfrak{p}}(m_1) = dv_p(m_1) \ge 2$ . It is contrary to the fact that  $v_{\mathfrak{p}}(\pi) = 1$ . Thus we have  $\mu = 1$  and  $v_{\mathfrak{p}}(z_j) = 1$  for some integer  $j \in \mathbb{Z}$  with  $2 \leq j \leq d$ . For such a number  $z_j$  the valuations  $v_{\mathfrak{p}}(z_j^i)$ with  $0 \leq i \leq d-1$  have distinct images by the natural map  $\mathbb{Z} \to \mathbb{Z}/d\mathbb{Z}, m \mapsto m$ (mod d). This means that the degree of the minimal polynomial of  $z_j$  over  $\mathbb{Q}$  is not less than d. Thus we have  $K = \mathbb{Q}(z_j)$ . Let  $f(X) = \sum_{i=0}^d a_i X^i \in \mathbb{Q}[X]$  be the minimal polynomial of  $z_j$  over  $\mathbb{Q}$ . If the set  $\{0 \leq i \leq d-1 | v_p(a_i) = 0\}$  is not empty, then  $v_{\mathfrak{p}}(f(z_j)) = \min\{0 \le i \le d-1 | v_p(a_i) = 0\} < \infty$ , which contradicts that  $f(z_j) = 0$ . Thus it satisfies that  $v_p(a_i) \ge 1$  for every  $0 \le i \le d-1$ . Then one has that  $v_{\mathfrak{p}}(a_0) = v_{\mathfrak{p}}(z_j^d) = d$ , which means  $v_p(a_0) = 1$ . Hence  $z_j$  is a p-Eisenstein number. 

### § 5. Some numerical examples

In this section we present some numerical examples of fields satisfying the six conditions (1) to (6) with explicit definition polynomials. Let us denote by  $\operatorname{Spl}_F f(X)$  the minimal splitting field of a polynomial  $f(X) \in F[X]$  over a field F.

We first consider the case that p = 229 and (n, r) = (2, 3). Here one has d = nr = 6. The quadratic field k contained in  $\mathbb{Q}(\zeta_p)$  is equal to  $\operatorname{Spl}_{\mathbb{Q}}g_0(X)$  where  $g_0(X) = X^2 - 229$ . The cyclic field L of degree d = 6 in  $\mathbb{Q}(\zeta_p)$  is  $\operatorname{Spl}_k g_1(X)$  for  $g_1(X) = X^3 - 4X - 1$  (cf. Cohen [1], Komatsu [6]). It is calculated that

 $\operatorname{Cl}(k) \simeq \mathbb{Z}/3\mathbb{Z}$  where  $\operatorname{Cl}(k)$  is the ideal class group of k. This means that there exists an unramified cyclic cubic extension M of k. One can see that M is equal to  $\text{Spl}_k g_2(X) = \text{Spl}_{\mathbb{Q}} g_2(X)$  where  $g_2(X) = X^3 - 687X - 5038$  (cf. Komatsu [5]). Now put E = LM. Then E is Galois over k with  $\operatorname{Gal}(E/k) \simeq (\mathbb{Z}/3\mathbb{Z})^2$ . Let  $\alpha_i$  and  $\beta_j$  be numbers in  $\overline{\mathbb{Q}}$  such that  $g_1(X) = \prod_{i=1}^3 (X - \alpha_i)$  and  $g_2(X) = \prod_{j=1}^3 (X - \beta_j)$ , respectively. Let  $\sigma_1$  and  $\sigma_2$  be elements in  $\operatorname{Gal}(E/k)$  so that  $\sigma_1 : \alpha_i \mapsto \alpha_i, \beta_1 \mapsto \alpha_i$  $\beta_2 \mapsto \beta_3 \mapsto \beta_1 \text{ and } \sigma_2 : \alpha_1 \mapsto \alpha_2 \mapsto \alpha_3 \mapsto \alpha_1, \beta_j \mapsto \beta_j \text{ for } i, j \in \{1, 2, 3\},$ respectively. Then it holds that  $L = E^{G_1}$ ,  $M = E^{G_2}$  and  $\operatorname{Gal}(E/k) = \langle \sigma_1, \sigma_2 \rangle$ where  $G_i = \langle \sigma_i \rangle$  for i = 1 and 2. Let us define  $\theta = \alpha_1 \beta_1 + \alpha_2 \beta_2 + \alpha_3 \beta_3 \in E$ . Then one has  $k(\theta) \subseteq E^{G_3}$  for  $G_3 = \langle \sigma_1 \sigma_2 \rangle$ . Note that  $G_3 \cap G_1 = G_3 \cap G_2 = 1$ and  $G_3 \simeq \mathbb{Z}/3\mathbb{Z}$ . One can see that the minimal polynomial h(X) of  $\theta$  over  $\mathbb{Q}$  is equal to  $X^6 - 16488X^4 - 136026X^3 + 67963536X^2 + 1121398344X - 30392443755$ . This implies that  $[\mathbb{Q}(\theta) : \mathbb{Q}] = 6$  and  $\mathbb{Q}(\theta) = k(\theta) = E^{G_3}$ , which is denoted by K. Theorem 1.3 shows that K satisfies the six conditions (1) to (6). By  $6 = d \mid (p-1)/2 = 114$ , the field K is totally real. Unfortunately, the number  $\theta$  is not p-Eisenstein since the constant term  $a_0$  of h(X) satisfies  $v_p(a_0) = 2$ . Theorem 1.3 implies that disc $(K/\mathbb{Q}) = 229^5$ . On the other hand, it is calculated that  $\operatorname{disc}_X h(X) = 2^{12} \cdot 3^{30} \cdot 229^{13} \cdot 24793^2$ . Let us put

$$x_1 = 1, x_2 = \theta, x_3 = \theta^2, x_4 = \theta^3/229, x_5 = \theta^4/229, x_6 = \theta^2(\theta^3/229 - 68)/229.$$

Then  $\{x_j\}_{j=1}^6 \subseteq \mathcal{O}_K$  is a free basis of  $\mathcal{O}_{K,\mathfrak{p}}$  over  $\mathbb{Z}_p$  with  $v_{\mathfrak{p}}(x_1) = 0$  where  $\mathfrak{p}$  is the prime ideal of K above p. The numbers  $c_2 = 0, c_3 = 0, c_4 = 68, c_5 = 0$  and  $c_6 = 158$  satisfy that  $x_1c_j \equiv x_j \pmod{\mathfrak{p}}$ , respectively. By putting  $z_j = x_j - x_1c_j$  one can see that  $v_{\mathfrak{p}}(z_2) = 2, v_{\mathfrak{p}}(z_3) = 4, v_{\mathfrak{p}}(z_4) = 2, v_{\mathfrak{p}}(z_5) = 2$  and  $v_{\mathfrak{p}}(z_6) = 1$ . The minimal polynomial f(X) of  $z_6$  over  $\mathbb{Q}$  is equal to

$$\begin{split} f(X) &= X^6 - 96180X^5 - 37394605380X^4 + 1703530969560862X^3 \\ &\quad +72724266171681226116X^2 + 147851737295298813149160X \\ &\quad +27821740949946705377847421 \\ &= X^6 - 2^2 \cdot 3 \cdot 5 \cdot 7 \cdot 229X^5 \\ &\quad -2^2 \cdot 3 \cdot 5 \cdot 11 \cdot 229 \cdot 401 \cdot 617X^4 \\ &\quad +2 \cdot 13 \cdot 229 \cdot 286115379503X^3 \\ &\quad +2^2 \cdot 3 \cdot 7 \cdot 229 \cdot 367 \cdot 853 \cdot 1213 \cdot 9956087X^2 \\ &\quad +2^3 \cdot 3 \cdot 5 \cdot 229 \cdot 5380339785127322167X \\ &\quad +229 \cdot 1519169 \cdot 79972878961273721, \end{split}$$

which is a *p*-Eisenstein polynomial. Thus  $z_6$  is a *p*-Eisenstein number with  $K = \mathbb{Q}(z_6)$ . The field  $\operatorname{Spl}_{\mathbb{Q}} f(X) = E$  is a Galois  $(\mathcal{D}_3 \times \mathcal{C}_3)$ -extension of  $\mathbb{Q}$  with degree 18. By using a calculator Pari-GP one can find a unit  $\varepsilon \in K$  whose minimal polynomial  $f_1(X)$  over  $\mathbb{Q}$  is equal to

$$f_1(X) = X^6 + 564X^5 + 76206X^4 + 70094X^3 - 21032X^2 + 346X + 1.$$

Then it satisfies that

 $f_1(X - 94) = X^6 - 56334X^4 + 4639998X^3 + 506979436X^2$ -75182965726X + 2442021793125 $= X^6 - 2 \cdot 3 \cdot 41 \cdot 229X^4 + 2 \cdot 3 \cdot 11 \cdot 229 \cdot 307X^3$  $+2^2 \cdot 229 \cdot 553471X^2 - 2 \cdot 11 \cdot 229 \cdot 14923177X$  $+3 \cdot 5^4 \cdot 229 \cdot 5687387.$ 

The prime numbers  $p \equiv 1 \pmod{12}$  less than 2000 with  $3 \mid h(\mathbb{Q}(\sqrt{p}))$  are p = 229, 733, 1129 and 1489 (cf. Komatsu [5]). In the same way as above one can calculate

$$\begin{array}{l} \textbf{Proposition 5.1. For $p=229$, 733, 1129 and 1489$, the zeros of polynomials} \\ X^6-56334X^4+4639998X^3+506979436X^2 \\ -75182965726X+2442021793125$, \\ X^6+1466X^5+517498X^4-215438962X^3-199612437946X^2 \\ -49974959030498X-4171953628526171$, \\ X^6-2258X^5+1287060X^4+402900585X^3-513889910560X^2 \\ +66733203945617X+19658366564838499$, \\ X^6-2978X^5-3195881178465X^4+3940122374968794844X^3 \\ -2048598115826151476248505X^2+504906652334980646172265142534X \\ -48608237799042834668269234616457255 \end{array}$$

are p-Eisenstein numbers, respectively. Such a p-Eisenstein number generates a non-Galois, totally real and sextic field with discriminant  $p^5$ .

Next consider the case that p = 277 and (n, r) = (3, 2). Then one has d = nr = 6. The cyclic cubic field k contained in  $\mathbb{Q}(\zeta_p)$  is equal to  $\operatorname{Spl}_{\mathbb{Q}}g_0(X)$  where  $g_0(X) = X^3 - 831X - 7202$  (cf. Cohen [1], Komatsu [6]). The cyclic field L of degree d = 6 in  $\mathbb{Q}(\zeta_p)$  is  $\operatorname{Spl}_k g_1(X)$  for  $g_1(X) = X^2 - 277$ . It is calculated that  $\operatorname{Cl}(k) \simeq (\mathbb{Z}/2\mathbb{Z})^2$ . This means that there exists an unramified quadratic extension of k. Let  $x \in k$  be a solution of  $g_0(X) = 0$  and put  $\xi = -(x^2 - 10x - 740)/9$ . Then the minimal polynomial of  $\xi$  over  $\mathbb{Q}$  is equal to  $\tilde{g}_0(X) = X^3 - 62X^2 + 81X - 4$ . Let us define  $g_2(X) = \tilde{g}_0(X^2)$ . Then  $M_1 = \operatorname{Spl}_{\mathbb{Q}}g_2(X)$  is an unramified Galois extension of k with  $\operatorname{Gal}(M_1/k) \simeq \operatorname{Cl}(k) \simeq (\mathbb{Z}/2\mathbb{Z})^2$ . Let  $\beta$  be a solution of  $g_2(X) = 0$ . Then

 $M = k(\beta)$  is an unramified quadratic extension of k. Now put E = LM. Then E is Galois over k with  $\operatorname{Gal}(E/k) \simeq (\mathbb{Z}/2\mathbb{Z})^2$ . Let  $\alpha$  be a solution of  $g_1(X) = 0$ . We define  $\theta = \alpha\beta \in E$ . In the same way as for the case (p, n, r) = (229, 2, 3), it is seen that  $K = \mathbb{Q}(\theta)$  satisfies the six conditions (1) to (6). The minimal polynomial h(X) of  $\theta$  over  $\mathbb{Q}$  is equal to

$$h(X) = \tilde{g}_0(X^2/277)277^3 = X^6 - 17174X^4 + 6215049X^2 - 85015732$$

Here h(X) is not a *p*-Eisenstein polynomial for  $v_{277}(85015732) = 3$ . In the same way as for (p, n, r) = (229, 2, 3) one can calculate that  $z_6 = \theta(26(\theta^2/277)^2 + 218(\theta^2/277) + 148)/277$  is a *p*-Eisenstein number with  $K = \mathbb{Q}(z_6)$ . The minimal polynomial of  $z_6$  over  $\mathbb{Q}$  is equal to

$$f(X) = X^{6} - 2605040960X^{4} + 2681576423424X^{2} - 12566269001728$$
  
=  $X^{6} - 2^{6} \cdot 5 \cdot 277 \cdot 29389X^{4} + 2^{16} \cdot 3^{3} \cdot 277 \cdot 5471X^{2} - 2^{28} \cdot 13^{2} \cdot 277.$ 

One can see that  $\operatorname{Spl}_{\mathbb{Q}} f(X) = LM_1$  is a Galois  $(\mathfrak{A}_4 \times \mathcal{C}_2)$ -extension of  $\mathbb{Q}$  with degree 24. By using a calculator Pari-GP one can find a unit  $\varepsilon \in K$  whose minimal polynomial  $f_1(X)$  over  $\mathbb{Q}$  is equal to

$$f_1(X) = X^6 - 83X^5 + 1093X^4 + 9510X^3 - 1093X^2 - 83X - 1.$$

Then it satisfies that

$$f_1(X+60) = X^6 + 277X^5 + 30193X^4 + 1603830X^3 +40439507X^2 + 334128757X - 1669299781 = X^6 + 277X^5 + 109 \cdot 277X^4 + 2 \cdot 3 \cdot 5 \cdot 193 \cdot 277X^3 +277 \cdot 145991X^2 + 31 \cdot 167 \cdot 233 \cdot 277X - 277 \cdot 1699 \cdot 3547.$$

Proposition 5.2. Every zero of the polynomial

$$\begin{array}{r} X^{6}+277X^{5}+30193X^{4}+1603830X^{3}\\ +40439507X^{2}+334128757X-1669299781\end{array}$$

is a 277-Eisenstein number which generates a non-Galois, totally real and 277-Eisenstein field of degree 6 with discriminant 277<sup>5</sup>.

We obtain the following polynomials by considering the unramified extensions of certain algebraic number fields in a similar way as above. Proposition 5.3. For p = 2713, 2777, 2857 and 3137, the polynomials  $X^4 - 2713X^2 - 2713X + 5426$ ,  $X^4 - 2777X^2 - 8331X - 5554$ ,  $X^4 - 5714X^2 - 22856X + 48569$ ,  $X^4 - 3137X^2 - 47055X - 156850$ 

are p-Eisenstein polynomials whose minimal splitting fields over  $\mathbb{Q}$  are Galois  $\mathfrak{S}_4$ extensions, respectively. Every zero of the above p-Eisenstein polynomial is a pEisenstein number which generates a non-Galois, totally real and quartic field with
discriminant  $p^3$ .

Let K be an algebraic number field of finite degree and  $\widetilde{K}$  the Galois closure extension of K over  $\mathbb{Q}$ . Let (d, G) be a pair of an integer d and a group G such that  $(d, G) = (5, \mathfrak{A}_5), (6, \mathfrak{S}_5), (6, \mathfrak{S}_6), (7, \mathrm{PSL}_2(\mathbb{F}_7))$  or  $(7, \mathfrak{A}_7)$ .

**Problem 5.4.** Do there exist any algebraic number fields K of degree d with  $\operatorname{Gal}(\widetilde{K}/\mathbb{Q}) \simeq G$  which satisfy all of the six conditions (1) to (6) ?
